

Course of Artificial Intelligence

Tasks to be completed (one per team)

1. Design and implement an intelligent agent in the context of telemedicine. Specifically, the program will have to manage a series of vital parameters and return a response message to the patient, as well as inform the doctor in the event of significantly unbalanced parameter values. Keep track of the various interactions that have taken place using a database.
2. In the context of the video surveillance architecture combining VLM and ISEQL, please implement and test the first two levels of the pipeline on video in different contexts (including homemade). As regards VLMs, you could use *qwen 2.5* or *other versions on ollama*, *gemini 1.5 robotics view on Google AI studio via API Key*, or any other tool deemed appropriate.
3. Define a system that allows users to define event models in ISEQL via a graphical interface. The system will generate the query as a regular expression in ISEQL, automatically understanding which ISEQL operator to call, and with which parameters if necessary. Please note that the output should be an ISEQL query, but it is not necessary to connect it to the database management system.

In order to take the exam, submit all documentation produced, which must contain a detailed description of all steps taken with the relevant reasons, as well as all sources of the code implemented within 57 hours of the date of the chosen exam session.

Although this is a group project, each member must still be able to explain in detail all of the documentation produced, including the code.
